Blocks, Grids, and Threads

- When a kernel is launched, CUDA generates a grid of threads that are organized in a three-dimensional hierarchy
  - Each grid is organized into an array of thread blocks or blocks
  - Each block can contain up to 1,024 threads
  - Number of threads in a block is given in the blockDim variable
  - The dimension of thread blocks should be a multiple of 32
- Each thread in a block has a unique threadIdx value
  - Combine the threadIdx and blockIdx values to create a unique global index
Blocks, Grids, and Threads

Global Thread IDs: 2D grid of 2D blocks

- $tx = threadIdx.x$
- $ty = threadIdx.y$
- $bx = blockIdx.x$
- $by = blockIdx.y$
- $bw = blockDim.x$
- $bh = blockDim.y$
- $id_x = tx + bx \times bw$
- $id_y = ty + by \times bh$
Blocks, Grids, and Threads

- **blockIdx**: The block index within the grid
- **gridDim**: The dimensions of the grid
- **blockDim**: The dimensions of the block
- **threadIdx**: The thread index within the block.

![CUDA Grid Diagram]

### Thread index

\[
\text{Thread index} = \text{threadIdx.x} + \text{blockIdx.x} \times \text{blockDim.x}
\]
Global Thread IDs: 3D grid of 3D blocks

- $tx = threadIdx.x$
- $ty = threadIdx.y$
- $tz = threadIdx.z$
- $bx = blockIdx.x$
- $by = blockIdx.y$
- $bz = blockIdx.y$
- $bw = blockDim.x$
- $bh = blockDim.y$
- $bd = blockDim.z$
- $id_x = tx + bx * bw$
- $id_y = ty + by * bh$
- $id_z = tz + bz * bd$

Blocks Must be Independent

- Any possible interleaving of blocks should be valid
  - presumed to run to completion without pre-emption
  - can run in any order
  - can run concurrently OR sequentially
- Blocks may coordinate but not synchronize
- Independence requirement gives scalability
Example 2: A Multi-Dimensional Grid

Processing a Picture with a 2D Grid
Row-Major Layout in C/C++

M

M

Source Code of a PictureKernel

__global__ void PictureKernel(float* d_Pin, float* d_Pout, int height, int width) {

    // Calculate the row # of the d_Pin and d_Pout element
    int Row = blockIdx.y*blockDim.y + threadIdx.y;

    // Calculate the column # of the d_Pin and d_Pout element
    int Col = blockIdx.x*blockDim.x + threadIdx.x;

    // each thread computes one element of d_Pout if in range
    if ((Row < height) && (Col < width)) {
        d_Pout[Row*width+Col] = 2.0*d_Pin[Row*width+Col];
    }
}

Host Code for Launching PictureKernel

// assume that the picture is m×n,
// m pixels in y dimension and n pixels in x dimension
// input d_Pin has been allocated on and copied to device
// output d_Pout has been allocated on device
...
dim3 DimGrid((n-1)/16 + 1, (m-1)/16+1, 1);
dim3 DimBlock(16, 16, 1);
PictureKernel<<<DimGrid,DimBlock>>>(d_Pin, d_Pout, m, n);
...

Covering a 62×76 Picture with 16×16 Blocks

Not all threads in a Block will follow the same control flow path.
**Transparent Scalability**

- Each block can execute in any order relative to others
  - Concurrently or sequentially
  - Facilitates scaling of the same code across many devices
- Hardware is free to assign blocks to any processor at any time
  - A kernel scales to any number of parallel processors

---

**Example 1: Executing Thread Blocks**

- Threads are assigned to *Streaming Multiprocessors (SM)* in block granularity
  - Up to 8 blocks to each SM as resource allows
  - Fermi SM can take up to 1536 threads
    - Could be 256 (threads/block) * 6 blocks
    - Or 512 (threads/block) * 3 blocks, etc.
- SM maintains thread/block idx #s
- SM manages/schedules thread execution
The Von-Neumann Model

The Von-Neumann Model with SIMD units

Single Instruction Multiple Data (SIMD)
Warp Example

- If 3 blocks are assigned to an SM and each block has 256 threads, how many Warps are there in an SM?
  - Each Block is divided into 256/32 = 8 Warps
  - There are 8 * 3 = 24 Warps
Blocks, Grids, and Threads

- Instructions are issued per warp
  - It takes 4 clock cycles to issue a single instruction for the whole warp
- If an operand is not ready the warp will stall
- Threads in any given warp execute in lock-step, but to synchronise across warps, you need to use `__syncthreads()`

Example: Thread Scheduling (Cont.)

- SM implements zero-overhead warp scheduling
  - Warps whose next instruction has its operands ready for consumption are eligible for execution
  - Eligible Warps are selected for execution based on a prioritized scheduling policy
  - All threads in a warp execute the same instruction when selected
Fermi Architecture

- Has 16 SM that each can process at most 8 blocks
- Each SM has 32 cores for a total of 512 cores

Block Granularity Considerations

- For Matrix Multiplication using multiple blocks, should we use 8X8, 16X16 or 32X32 blocks for Fermi?
  - For 8X8, we have 64 threads per block.
    - We will need 1536/64 = 24 blocks to fully occupy an SM since each SM can take up to 1536 threads
    - However, each SM has only 8 Blocks, only 64x8 = 512 threads will go into each SM!
    - This means that the SM execution resources will likely be underutilized because there will be fewer warps to schedule around long latency operations.
Block Granularity Considerations

- For Matrix Multiplication using multiple blocks, should I use 8X8, 16X16 or 32X32 blocks for Fermi?
  - For 16X16, we have 256 threads per Block. Since each SM can take up to 1536 threads, it can take up to 6 Blocks and achieve full capacity unless other resource considerations overrule.
  - For 32X32, we would have 1024 threads per Block. Only one block can fit into an SM for Fermi. Using only 2/3 of the thread capacity of an SM.

Each Kepler SMX contains 4 Warp Schedulers, each with dual Instruction Dispatch Units. A single Warp Scheduler Unit is shown above.
Performance Tuning

- For optimal performance, the programmer has to juggle
  - finding enough parallelism to use all SMs
  - finding enough parallelism to keep all cores in an SM busy
  - optimizing use of registers and shared memory
  - optimizing device memory access for contiguous memory
  - organizing data or using the cache to optimize device memory access for contiguous memory

Example: Cooperating Threads

- Memory Management
  - Blocks
  - Threads
  - Indexing
  - Shared memory
    - __syncthreads()
  - Asynchronous operation
  - Handling errors
  - Managing devices
1D Stencil

- Consider applying a 1D stencil to a 1D array of elements
  - Each output element is the sum of input elements within a radius
- If radius is 3, then each output element is the sum of 7 input elements:

Implementing Within a Block

- Each thread processes one output element
  - blockDim.x elements per block

- Input elements are read several times
  - With radius 3, each input element is read seven times
Sharing Data Between Threads

- Terminology: within a block, threads share data via shared memory
- Extremely fast on-chip memory, user-managed
- Declare using `__shared__`, allocated per block
- Data is not visible to threads in other blocks

Implementing With Shared Memory

- Cache data in shared memory
  - Read `(blockDim.x + 2 * radius)` input elements from global memory to shared memory
  - Compute `blockDim.x` output elements
  - Write `blockDim.x` output elements to global memory
  - Each block needs a halo of radius elements at each boundary
1D Stencil Computation Example, Radius = 1

// assume u[i] initialized to some values
for (s=1; s<T; s+=2) {
    for (i=1; i<(N-1); i++) {
        tmp[i] = 1/3 * (u[i-1] + u[i] + u[i+1]); // S1
    }
    for (j=1; j<(N-1); j++) {
    }
}

__global__ void stencil_1d(int *in, int *out) {
    __shared__ int temp[BLOCK_SIZE + 2 * RADIUS];
    int gindex = threadIdx.x + blockIdx.x * blockDim.x;
    int lindex = threadIdx.x + RADIUS;

    // Read input elements into shared memory
    temp[lindex] = in[gindex];
    if (threadIdx.x < RADIUS) {
        temp[lindex - RADIUS] = in[gindex - RADIUS];
        temp[lindex + BLOCK_SIZE] = in[gindex + BLOCK_SIZE];
    }

    // Apply the stencil
    int result = 0;
    for (int offset = -RADIUS; offset <= RADIUS ; offset++)
        result += temp[lindex + offset];

    // Store the result
    out[gindex] = result;
}
Data Race!

- The stencil example will not work...
- Suppose thread 15 reads the halo before thread 0 has fetched it...

```c
temp[lindex] = in[gindex];
if (threadIdx.x < RADIUS) {
    temp[lindex - RADIUS] = in[gindex - RADIUS];
    temp[lindex + BLOCK_SIZE] = in[gindex + BLOCK_SIZE];
}
int result = 0;
result += temp[lindex + 1];
```

```c
__syncthreads();
```

- void __syncthreads();

- Synchronizes all threads within a block
  - Used to prevent RAW / WAR / WAW hazards

- All threads must reach the barrier
  - In conditional code, the condition must be uniform across the block
__global__ void stencil_1d(int *in, int *out) {
    __shared__ int temp[BLOCK_SIZE + 2 * RADIUS];
    int gindex = threadIdx.x + blockIdx.x * blockDim.x;
    int lindex = threadIdx.x + radius;

    // Read input elements into shared memory
    temp[lindex] = in[gindex];
    if (threadIdx.x < RADIUS) {
        temp[lindex - RADIUS] = in[gindex - RADIUS];
        temp[lindex + BLOCK_SIZE] = in[gindex + BLOCK_SIZE];
    }

    // Synchronize (ensure all the data is available)
    __syncthreads();
    // Apply the stencil
    int result = 0;
    for (int offset = -RADIUS ; offset <= RADIUS ; offset++)
        result += temp[lindex + offset];

    // Store the result
    out[gindex] = result;
}
